

Equidistribution of zeros of optimal approximants

Daniel Seco

Talk given at Seminar on Complex Analysis,
meeting 2290, January 11, 2021

When studying invariant subspaces for the shift, a special role is played by a class of polynomials called optimal approximants. It has been conjectured initially that the zeros of such approximants follow a special pattern. We show that not to be as expected, at least in the simplest cases: in fact, the zeros are equidistributed, making their pattern "less exceptional".
